20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

A series of wind tunnel tests were conducted using a parametric family of 2-, 3-, and 4-caliber hemisphere-tangent ogive cylinders with variations in midsection fineness ratios of 5, 7, 9, and 11 and nose bluffness variations of R_N/R_B = 0, 0.25, 0.50, 0.75 over a Mach number regime of M = 0.6 → 4.0. These data should be useful in preliminary design studies requiring bodies with bluff noses for radomes or optical lenses. Data were also obtained at selected test conditions for other nose configurations which included three

PREFACE

This report documents a series of wind tunnel tests conducted at Arnold Engineering Development Center for the Air Force Armament Laboratory, Armament Development and Test Center, Eglin Air Force Base, Florida 32542, under Projects 2069 and 670E from March 1971 to February 1976. The effort was jointly sponsored by the Air Force Armament Laboratory (DLMA), the Flight Dynamics Laboratory, and the Army Missile Command. Individuals who have contributed significantly to this project are Messrs. E. G. Allee, (ARO), John Jordan (ARO), and George Landingham (MICOM).

This report has been reviewed and is approved for publication.

SECTION I

INTRODUCTION

This report summarizes wind tunnel test data on various body alone configurations which provide a data matrix for bluff and pointed bodies of revolution with systematic variations in nose bluffness, nose fineness ratio, and cylinder afterbody fineness ratio. Modular model components were used to obtain static stability and drag data, with emphasis on the effect of nose bluffness on drag. Although data is included for tangent ogive noses of fineness ratio 2, 2.25, 2.5, 3.0, and 4, the nose fineness ratios of 2, 3, and 4 calibers include a systematic variation in nose bluffness ratios (R_N/R_B) of 0.00, 0.25, 0.50, and 0.75 on cylindrical midsections of 5, 7, 9, and 11 calibers. A 1-caliber cylindrical afterbody (AI7) is used with all configurations in this report.

SECTION II

APPARATUS

1. Wind Tunnel

The tests were conducted in the AEDC PWT/1T, and VKF/A continuous flow test facilities at the Arnold Engineering Development Center. The (1T) is a 12-inch-square perforated test section. The 40-inch supersonic test facility utilizes a solid wall test section. Detailed descriptions of the tunnels are given in Reference 1 and typical model installations are shown in Figures 1 and 2.

2. Test Articles

The test articles consisted of interchangeable nose, midsection, and afterbody configurations: 20 nose configurations, 4 cylindrical midsections of fineness ratio ranging from 5 to 11 and a 1-caliber cylindrical afterbody configuration as shown in Figures 3 and 4. Nose fineness varied from 1 to 4 calibers. Two-, 3- and 4-caliber tangent ogive noses (N14 through N25) were truncated and hemispherical nose caps added to provide three bluffness variations (R_N/R_B = 0.25, 0.50, 0.75). Grit or other means of fixing transition were not used to eliminate the drag increment due to the trip and also incremental drag changes resulting from loss of the grit during tunnel operations.

Although only a 1-caliber cylindrical afterbody is considered in this report, various fin configurations were utilized in previous transonic tests (References 2, 3, and 4), which include data for body-cruciform fin configurations with noses N10, N13, and N14. Scale effects utilizing a larger body-fin configuration in the 4T test facility are shown in Reference 5.

A typical assembly of model components is shown in Figure 4. The cylindrical midsections and noses were fabricated from stainless steel (type 303) with a 32-microinch surface finish. Model configuration identifications are shown in Table 1.

3. Instrumentation PWT/1T Test Facility

The internal balance used to measure the model aerodynamic loads in the (1T) test facility is shown in Figure 5. Base pressures were measure with two differential pressure transducers. Angle of attack measurements were corrected for support system and balance deflections.

4. Instrumentation VKF/A Test Facility

Two internal strain gage balances were used to measure the model

aerodynamic loads in the VKF/A wind tunnel test facility (Figures 6 and 7). The balance shown in Figure 6 was used in the initial test entry (Part Numbers 1 through 247). The balance shown in Figure 7 was used for the second test entry (Part Numbers 248 through 338).

Base pressures were measured with three differential pressure transducers and averaged by the use of fast response pressure transducers located near the model which allowed base static pressure data to be obtained during a continuous pitch sweep. Several pitch-pause sweeps were compared with continuous sweeps to insure that the inherent lag in the base pressure orifice and tubing did not degrade the data.

Angle of attack measurements were corrected for support system and balance deflections. Seventy mm Schlieren photographs were obtained for most configurations at angle of attack increments of approximately 4 degrees. Typical photographs are shown in Figure 8.

SECTION III

TEST DESCRIPTION

1. Test Procedures and Conditions

During each data run, the model angle of attack was varied while the roll angle and Mach number were held constant.

Static force data were obtained at angles of attack from -6 to +15 degrees. The transonic tests were conducted at Mach numbers of 0.6, 0.8, 1.0, 1.2, and 1.5. Nominal test conditions were stagnation temperature varied from 150 to 200°F, total pressure varied from 19.3 to 20.7 psia, and dynamic pressure varied from 3.82 to 8.85 psia as Mach number varied from 0.6 to 1.5, respectively. The supersonic tests were conducted at Mach numbers of 1.5, 2.0, 2.5, 3.0, 3.5, 4.0, and 4.5 with the major portions of the data at Mach numbers 1.5, 2.0, 3.0, and 4.0. Nominal test conditions were stagnation temperature 120°F, total pressure varied from 6.5 to 28.0 psia, and dynamic pressure varied from 2.80 to 1.37 psia as Mach number varied from 1.5 to 4.5, respectively.

The moment reference location for all configurations was the nose-body juncture of the model as shown in Figure 4. Sign conventions are shown in Figure 9.

The variation of nominal Reynolds number with Mach number is shown in Figure 10 for the PWT/1T and VKF/A test facilities. The difference in the test Reynolds numbers between the transonic and supersonic test facility should be noted in the comparison of data results at $M_\infty = 1.5$. The (1T) test facility does not have a variable density capability. The unit Reynolds number used in the supersonic test phase was $R_e/ft = 1.8 \times 10^6$ for all Mach numbers.

2. Data Uncertainties (Transonic Test Phase)

Data accuracy is affected by uncertainties in tunnel conditions and balance measurements. The random measurement errors are used to provide a measure of the uncertainty in the data measurements. The systematic measurement errors (bias) were assumed to be negligible for the transonic test phase. The table shown below provides the data uncertainties, assuming a 95 percent confidence level. The precision of setting and maintaining angle of attack is estimated to be ±0.1 degree. The methods used to calculate the uncertainties are given in References 4 and 5.

THIS DOCUMENT PROVIDED BY THE ABBOTT AEROSPACE
TECHNICAL LIBRARY
ABBOTTAEROSPACE.COM

UNCERTAINTY ± [(1T) TRANSONIC TEST PHASE]

Measured Coefficient Value

M	ΔC_N	ΔC_m	ΔC_y	ΔC_n	ΔC_l	C_{A_T}	C_{A_F}
0.6	0.03	0.03				0.03	
0.8	0.02	0.02				0.02	
1.0	0.02	0.02				0.02	
1.2	0.01	0.01				0.01	
1.5	0.01	0.01				0.01	

3. Data Uncertainties (Supersonic Test Phase)

The general procedure used to calculate the data uncertainty is the same as that used in the transonic test phase. The precision of setting and maintaining angle of attack is estimated to be ±0.1 degree. The data uncertainties shown in the tables below include both systematic measurement errors (bias) and random error measurements. Two separate tables are provided for the two test entries which utilized two different internal six-component strain gage balances.

4. Part Numbers for Specific Configurations in Tabulated Data

Tabulation data for the transonic and supersonic test phases are listed in Appendices A and B. Table 2 may be used to determine the part number for a specific configuration and Mach number. The part numbers are listed consecutively in the appendices for each test phase. Each part includes a sequence of angles of attack at a given Mach number.

SECTION IV

DATA

1. Tabulated Data

The appendices include tabulated force and moment data for all nose-cylinder body alone configurations used in the transonic and supersonic test phases. Due to the extensive data included in this report, data plots are not included for all configurations. Plotted data for the transonic test phase are included in Reference 7. All of the tabulated data in both appendices are shown for nominal zero roll angle and zero sideslip angle unless noted otherwise.

2. Transonic Data

All transonic data obtained in the (1T) test facility are included in Appendix A. The transonic data includes only 2-, 3-, and 4-caliber tangent ogive noses (N14 through N25) on midsections (M5 and M9). All configurations included the one-caliber afterbody (A17).

For increasing nose bluffness, the center of pressure is moved downstream on the model and the forebody axial force coefficient is also increased. The effect of increasing nose fineness ratio is to move the center of pressure upstream and also to decrease the forebody axial force coefficient at Mach numbers 1.0, 1.2, and 1.5, with minimal effect at Mach numbers of 0.6 and 0.8. Increasing body midsection fineness ratio from 5 to 9 does not significantly affect C_N for Mach numbers of 0.6 to 1.5, but does increase the forebody axial force coefficient.

3. Supersonic Data

The major portion of the supersonic data was also obtained for the 2-, 3-, and 4-caliber tangent noses and midsection including 5-, 7-, 9-, and 11-caliber lengths; in all cases the 1-caliber afterbody was included. In addition, the supersonic test phase includes data at selected test conditions for a hemisphere nose (N10), 2.25-caliber tangent ogive noses (R_N/R_B = 0.00, 0.375, 0.575), 2.5-caliber tangent ogive nose (N28), and two 2.25-caliber power series noses (N30 and N31). Table 3 provides a summary of forebody axial force coefficent, normal force coefficient slope, and pitching moment coefficient slope for all configurations. Plotted data for the forebody axial force coefficients, normal force coefficient slope, pitching moment coefficient slope, and center of pressure are shown in Figures 11 through 26 for the 2-, 3-, and 4-caliber noses on a 9-caliber midsection and 1-caliber afterbody.

Comparisons of the 2-, 3-, and 4-caliber nose at supersonic Mach numbers in Figure 11 show that the effect of bluntness on drag is more pronounced with increasing supersonic Mach numbers.

The variation in forebody axial force coefficient with nose bluffness ratio is shown in Figure 12. The pronounced increase in C_{A_F} for bluffness ratios ≥ 0.5 is apparent for a given supersonic Mach number.

Figure 13 shows the variation in forebody axial force coefficient with nose fineness ratio. C_{A_F} generally decreases with increasing supersonic Mach numbers and increasing midsection length increases C_{A_F} as shown in Figure 14.

The variation in the normal force slope with Mach number is shown in Figure 15 for various noses. The effect of nose bluntness on C_{N_α} is more pronounced with increasing supersonic Mach numbers.

The variation in the normal force slope with nose bluffness ratio is shown in Figure 16 for various noses. For a given supersonic Mach number, C_{N_α} generally decreases with increasing nose bluffness.

The variation in the normal force slope with nose fineness ratio is shown in Figure 17 for various noses. For a given supersonic Mach number, C_{N_α} generally decreases slightly with increases in nose fineness ratio.

An increase in midsection length increases C_{N_α} as shown in Figure 18.

The variation in the pitching moment slope with Mach number is shown in Figure 19 for various noses. Aft movement of the center of pressure past the nose cylinder juncture is apparent. C_{m_α} generally decreases with increasing nose bluffness ratios as shown in Figure 20.

The variation in pitching moment slope with nose fineness ratio is shown in Figure 21. C_{m_α} increases with increasing nose fineness ratio.

An increase in midsection length decreases C_{m_α} as shown in Figure 22.

The variation in normal force coefficient with angle of attack for a 3-caliber pointed tangent ogive cylinder and hemisphere tangent ogive cylinder ($R_N/R_B = 0.75$) is shown in Figure 23(a). The effect of nose bluntness over angle of attack range of -6 to 14 degrees is small for a Mach number of 1.5, but a reduction in normal force coefficient is evident for $M_\infty = 4.0$. A comparison of 2- and 4-caliber noses at a given angle of attack shows a lower C_N value for the higher fineness ratio nose as shown in Figure 23(b).

The variation in pitching moment with angle of attack for a 4-caliber pointed tangent ogive cylinder and hemisphere tangent ogive cylinder

TECHNICAL LIBRARY
ABBOTTAEROSPACE.COM

(R_N/R_B = 0.75) is shown in Figure 24(a). The abrupt change in the pitching moment curve at $\alpha \sim 4°$ is believed to be associated with flow separation on the cylinder. Schlieren photographs generally indicated flow separation for $\alpha > 5°$. The effect of increasing nose bluffness results in more negative pitching moment coefficient as angle of attack is increased. This latter effect is more pronounced with increasing supersonic Mach numbers. Given an increase in nose fineness ratio, C_m is increased for a given α as shown in Figure 24(b).

The variation in center of pressure with angle of attack for a 3-caliber pointed tangent ogive cylinder and hemisphere-ogive cylinder (R_N/R_B = 0.75) is shown in Figure 25(a). The center of pressure moves further downstream at a given angle of attack for the bluff configuration. This latter effect is more pronounced with increasing supersonic Mach numbers. With increasing nose fineness ratio, the center of pressure moves further upstream as shown in Figure 25(b).

The variation of forebody axial force coefficient with Mach number is shown in Figure 26 for a series of 2.25-caliber noses. Data includes two hemisphere-tangent ogives and two power series noses. C_{A_F} for the power series nose (N30) is less than the C_{A_F} for the pointed tangent ogive nose (N26).

4. Supersonic Laminar Skin Friction Calculations and Nose Wave Drag

Test Reynolds numbers were selected to retain a laminar boundary layer over full body length at supersonic Mach numbers. Theoretical skin friction coefficients were calculated by VKF personnel and are given in Table 4 for various body lengths, nose bluntness, and nose lengths. Calculated model wetted areas are used in the calculations in Table 5. The method used for the skin friction calculations was based on reference by Patankar and Spalding as modified by Mayne and Dyer (References 9 and 10). A comparison of C_{A_F} determined from experimental and typical handbook methods such as the USAF Stability and Control Datcom is shown in Figure 27 (Reference 11). The nose pressure drag coefficient was calculated by subtracting the calculated laminar skin friction drag coefficient from the measured forebody axial force coefficient. It should be noted that a fully laminar boundary layer was assumed over the full model length for these calculations and transition was not indicated from the Schlieren photographs or drag measurements. The agreement between the data and the Datcom method improves with increasing Mach number and nose fineness ratio.

SECTION V

RECOMMENDATIONS FOR FUTURE TASKS

1. Assess the methodologies described in References 12 and 13 as predictive techniques for the static aerodynamic characteristics of bluff body alone configurations. The data matrix in this report should be useful in assessing these methods.

2. Determine the Reynolds number effects on the drag and static stability characteristics for selected nose configurations on the 5- and 9-caliber midsection with Reynolds numbers ranging up to 20×10^6/ft for the existing model sizes and selected larger models similar to that in Reference 5.

3. Measure pressure distributions on selected nose configurations using the larger model scale noted above and the 5-caliber midsection at selected Reynolds numbers to determine C_{A_p} and utilize oil flow techniques to locate separation and heating rate measurements to locate transition.

4. Obtain additional data for nose bluffness ratio variations of R_N/R_B = 0.00 to 0.20 to define the degree of bluffness which will result in a minimum forebody pressure axial force (C_{A_p}) for the 2.3- and 4-caliber noses. Also obtain force and moment data for 1-caliber tangent ogive family with bluffness ratios of 0.25, 0.50, and 0.75.
