configurations are also presented. Data are presented for various combinations of the Tactical Electronic Warfare System Pods (TEWS), the AIM-7F, the 600-gal fuel tanks, the GBU-15 (CW), the SUU-30H/B, and the Advance Short Range Missile (ASRM) stores. Data are presented for Mach numbers ranging from 0.6 to 1.3 at angles of attack from -4 to 20 deg at zero-deg sideslip angle, and for sideslip angles from -4 to 10 deg at angles of attack of 0, 10, 15, and 20 deg.

PREFACE

The work reported herein was conducted at the Arnold Engineering Development Center (AEDC), Air Force Systems Command (AFSC), at the request of the Air Force Armament Laboratory (AFATL/DLJC) under Program Element 62602F, Project 2567, Task 02. The AFATL project monitor was Major R. E. VanPutte. The results of these tests were obtained by ARO, Inc., AEDC Division (a Sverdrup Corporation Company), operating contractor for the AEDC, AFSC, Arnold Air Force Station, Tennessee, under ARO Project No. P41C-A3A. The author of this report was James M. Whoric, ARO, Inc. The data analysis was completed on November 13, 1975, and the manuscript (ARO Control No. ARO-PWT-TR-76-14) was submitted for publication on February 9, 1976.

1.0 INTRODUCTION

Wind tunnel tests were conducted to establish a data base on the effects of external stores on the aerodynamic characteristics of the F-15. The tests were conducted in the Aerodynamic Wind Tunnel (4T) of the AEDC Propulsion Wind Tunnel (PWT) facility utilizing 0.05-scale models of the F-15 aircraft, the Tactical Electronic Warfare System (TEWS) pods, the 600-gal fuel tanks, the GBU-15 (CW), the AIM-7F, the SUU-30H/B, and the Advance Short Range Missile (ASRM) stores. Static longitudinal stability and drag data were obtained for all external store configurations at Mach numbers ranging from 0.6 to 1.3. Angle of attack was varied from -4 to 20 deg at a sideslip angle of zero deg. Lateral-directional stability data were obtained for selected configurations over the same Mach number range. For these data, the sideslip angle was varied from -4 to 10 deg at angles of attack of 0, 10, 15, and 20 deg.

2.0 APPARATUS

2.1 TEST FACILITY

The Aerodynamic Wind Tunnel (4T) is a closed-loop, continuous-flow, variable-density tunnel in which the Mach number can be varied from 0.1 to 1.3. Also, nozzle blocks can be installed to give nominal Mach numbers of 1.6 and 2.0. At all Mach numbers, the stagnation pressure can be varied from 300 to 3,700 psfa. The test section is 4 ft square and 12.5 ft long with perforated, variable porosity (0.5- to 10-percent open) walls. It is completely enclosed in a plenum chamber from which the air can be evacuated, allowing part of the tunnel airflow to be removed through the perforated walls of the test section. A more complete description of this test facility can be found in the Test Facilities Handbook.*

The tunnel 4T support system for the models consists of a pitch sector with strut and sting attachment which has a pitch capability of -8 to 28 deg with respect to the tunnel centerline and a roll capability of -180 to 180 deg with respect to the sting centerline.

2.2 TEST ARTICLES

The test articles were 0.05-scale models of the F-15 aircraft, the 600-gal fuel tanks, the Tactical Electronic Warfare System (TEWS) pods, the AIM-7F, the GBU-15 (CW), the SUU-30H/B, the Advance Short Range Missile (ASRM) stores, and associated suspension

*Test Facilities Handbook (Tenth Edition). "Propulsion Wind Tunnel Facility, Vol. 4." Arnold Engineering Development Center, May 1974.

equipment. A photograph of the F-15 configured with the SUU-30H/B stores, the AIM-7F stores, and the centerline 600-gal fuel tank is shown in Fig. 1. Sketches of the F-15 model and wing panel are presented in Figs. 2 and 3. Two flow-through inlet configurations were used during these tests. Sketches showing the basic dimensions of these inlets are presented in Fig. 4. The store suspension equipment used with the various stores is shown in Fig. 5. The TEWS, the 600-gal fuel tanks, and the GBU-15 (CW) stores were all suspended from the F-15 using appropriate pylons (Figs. 5a, b, and c). The ASRM stores were mounted in tandem and required a special pylon adapter (Fig. 5d) for proper suspension, whereas, a MER (Fig. 5e) was used in conjunction with a pylon for the SUU-30H/B store suspension. The AIM-7F stores were fuselage mounted. Details and dimensions of the 0.05-scale models of the various external stores mentioned above are shown in Fig. 6. A configuration identification key is presented in Fig. 7. Shown in that figure along with the aircraft load configuration are store profiles scaled with respect to each other. The configurations are identified numerically for reference in the remainder of this report.

2.3 INSTRUMENTATION

A six-component, internal, strain-gage balance was used to measure the forces and moments on the F-15 model. Two base pressure measurements were made using transducers and orifice tubes which extended just inside of the base of the model.

3.0 TEST DESCRIPTION

3.1 TEST CONDITIONS, PROCEDURES, AND TEST PROGRAM

The models were tested at the following nominal test conditions:

<u>M_∞</u>	<u>p_t, psfa</u>	<u>$Re \times 10^{-6}$, per foot</u>
0.6	1,200	1.94
0.8	↓	2.30
0.9	↓	2.42
1.1	↓	2.53
1.3	↓	2.50

In addition, configurations 101, 201, and 206 were also tested at $M_\infty = 0.85, 0.95, 0.975,$ and 1.2.

The test procedures were conventional in nature, consisting of varying the model angle of attack incrementally at a constant sideslip angle, or varying the model angle of

sideslip at a constant angle of attack while holding the Mach number constant. The model stabilator angle was held constant at zero deg with respect to a model waterline throughout the test.

The test program that was completed is presented in Table 1. As indicated, configuration 218 was not tested because of a fin interference problem. This table provides a key to all the wind tunnel data obtained during these tests.

3.2 DATA REDUCTION AND CORRECTIONS

Wind tunnel force and moment data were reduced to coefficient form in the stability axis system. Base drag was calculated using an average of two base pressure measurements and was used to calculate forebody coefficients. However, all data presented in this report are measured coefficients. Moments were referenced to MS 27.86 (25.65-percent MAC), WL 5.81, and BL 0. Corrections for the components of model weight normally termed static tares were also applied to the data.

The angle of attack was corrected for sting and balance deflections caused by the aerodynamic loads. The model was tested both upright and inverted to provide the data to correct for tunnel-flow angularity and model-balance misalignment. Based on these data, the angle of attack was corrected as indicated by the data presented in Fig. 8.

3.3 DATA UNCERTAINTY

The data uncertainties determined for a confidence level of 95 percent are presented in Table 2. The aerodynamic coefficient uncertainties include the uncertainties of Mach number and dynamic pressure along with the uncertainty contribution associated with the particular balance. Model angle of attack uncertainty has been estimated to be ± 0.1 deg and model roll angle ± 0.4 deg.

4.0 TEST RESULTS, ANALYSIS, AND DISCUSSION

Presented in the following sections is a discussion of the effect of the inlet configuration and the effect of various store configurations on the static longitudinal stability, drag, and lateral-directional stability derivatives of the F-15 model. Coefficient data as well as incremental data are presented and discussed.

The static margins were evaluated by taking the slope of a least-squares fit of the pitching-moment coefficient versus lift-coefficient curve over the nominal angle-of-attack range from -2 to 6 deg. All static margin characteristics are given from the general moment reference point of 25.65-percent chord and do not consider the actual flight center of gravity, which may be substantially changed by the addition of stores.

Drag coefficients were evaluated at specific lift coefficients from curve fits of the data, from which the drag increments were then calculated. Lateral-directional derivatives were also evaluated from least-squares curve fits of the data over the sideslip-angle range from -4 to 4 deg.

4.1 EFFECT OF THE INLET CONFIGURATION ON THE LONGITUDINAL STABILITY AND DRAG

Since the F-15 inlet configuration varies with aircraft angle of attack, the F-15 model was initially tested with two inlet configurations. One inlet configuration was representative of the low angle-of-attack configuration, and the other was representative of the high angle-of-attack configuration (Fig. 4).

A comparison of the data obtained with the F-15 model configured with these two inlet configurations (Figs. 9 and 10) shows that the static longitudinal stability as determined by the slope of pitching-moment coefficient versus lift coefficient curve was generally independent of inlet configuration for lift coefficients up to about 0.6. However, the high alpha inlet did show a more negative zero-lift pitching-moment coefficient when compared with the low alpha configuration. At lift coefficients greater than 0.6, the F-15 with the high alpha inlet configuration was somewhat more stable longitudinally than with the low alpha inlet configuration. The drag was also lower (Fig. 10) with the high alpha inlet than with the low alpha inlet. Based on the results of these data, the decision was made to conduct the remainder of the test with the model configured with the high alpha inlet.

4.2 EFFECT OF EXTERNAL STORE CONFIGURATIONS ON STATIC LONGITUDINAL STABILITY

To assess the effects of the various external store configurations on the static longitudinal stability of the F-15 aircraft, four configurations were selected as baseline configurations. They were configuration 201 (clean, no stores or suspension equipment), configuration 210 (AIM-7F and centerline 600-gal fuel tank), configuration 211 (AIM-7F only), and configuration 215 (centerline 600-gal fuel tank only). The pitching-moment coefficient data for these baseline configurations and the static margins derived from these data are presented in Figs. 11 and 12. The data that will be used in the discussion of the effects of various external stores on the static longitudinal stability will be presented as incremental changes in static margin as various stores are added symmetrically to the armament stations of the F-15 model. When store-alone increments are available (i.e., increments measured without stores present at the other armament station), the incremental data are presented as direct comparison of the static margin change produced when a

particular store is added to the F-15 at a particular armament station alone, to the static margin change produced by that same store at the same armament station when stores were present at the other armament stations. For those stores for which store-alone increment data were not obtained, the incremental data are presented as single curves for the various configurations for comparison. As an additional aid in identifying the data, the numbers of the two configurations for which the increments were calculated are listed in the header information of each plot. For example, in Fig. 13, the data represented by the squares are the incremental changes in static margin which were measured when the TEWS stores were added to the clean aircraft at armament stations 1 and 9. These increments were calculated by taking the difference between the static margin calculated for configurations 202 and 201 at each test Mach number. In Fig. 13a, the data represented by circles are also the incremental changes produced by adding the TEWS stores to the F-15 at stations 1 and 9, but with the F-15 carrying the centerline 600-gal fuel tank. Similarly, in Figs. 13b and c, the circles present the static margin increments produced by the TEWS at stations 1 and 9 with the model configured with different stores at the other stations.

The data obtained for adding stores to the F-15 outboard wing stations (1 and 9) are presented in Fig. 13, to the inboard wing stations (2 and 8) in Figs. 14 through 18, to the fuselage stations (3, 4, 6, and 7) in Fig. 19, and to the fuselage centerline station (5) in Fig. 20. These data show that when external stores were added symmetrically to the F-15 aircraft at any of the armament stations, except the fuselage centerline (station 5), the effect was always destabilizing and essentially independent of Mach number. Static margin changes of from 2- to 3-percent chord were produced by the store configurations suspended on the wing stations with the MER-mounted SUU-30H/B stores producing the largest change (Fig. 17). The AIM-7F stores at the fuselage stations (3, 4, 6, and 7) produced smaller changes in static margin than the stores that were added to the wing armament stations. At the centerline fuselage station (5), the data in Fig. 20 show that the centerline 600-gal fuel tank usually had a stabilizing effect on the F-15 model.

In general, the changes in static margins which were produced by adding specific stores to any armament station on the clean configuration were larger than when the same stores were added to the F-15 with stores present at the other armament stations. This fact is further illustrated by the data presented in Fig. 21. A comparison is shown between the static margin change measured for configurations 206 and 217 and the static margin change that was computed by adding the static margin increments measured when each external store in the configuration was carried alone on the F-15 aircraft. Summing the individual components over-predicted the static margin change actually measured for these two configurations, except at Mach number 1.3. Also noteworthy is the fact that the data in Fig. 21a at Mach numbers 0.95 and 0.975 show that the destabilizing effect of the external stores of configuration 206 decreased until finally a stabilizing effect was noted at Mach number 0.975.

4.3 EFFECTS OF EXTERNAL STORE CONFIGURATIONS ON THE DRAG CHARACTERISTICS

The data which show the effects of the various external store configurations on the drag characteristics of the F-15 are presented in Figs. 22 through 30 as a function of lift coefficient. As with the longitudinal stability data, the wind tunnel coefficient data of the baseline configurations are presented first (Fig. 22), and then the incremental changes in the drag coefficients for the various configurations are presented. The data presentation for the drag effects discussion will follow the same format as for the stability discussion. Incremental changes in drag coefficient caused by adding stores symmetrically to the outboard wing stations (1 and 9) are presented in Fig. 23, to the inboard wing stations (2 and 8) in Figs. 24 through 28, to the fuselage stations (3, 4, 6, and 7) in Fig. 29, and to the centerline fuselage station (5) in Fig. 30.

These data show that the addition of external stores to the F-15 to any armament station always produced an increase in drag at low values of lift coefficients ($0 \leq C_L \leq 0.6$). This was also generally true at the higher values of lift coefficients, but there were some cases of drag reduction ($\Delta C_D < 0$) noted in the high lift coefficient range (Fig. 23). Moreover, in the high lift coefficient range, larger drag increments were generally noted when stores were added to the F-15 with stores present at the other armament stations than were noted without stores present at the other armament stations. This effect was most pronounced at Mach numbers 1.1 and 1.3.

It is also of interest to determine whether the drag increments for external store configurations consisting of different stores or store configurations at several armament stations can be predicted by adding up the drag increments measured when each store or store configuration of the multiple carriage configuration was carried alone by the F-15 aircraft. A comparison of such a summation of drag increments to the total drag increment measured for configurations 217 and 206 is presented in Fig. 31. These comparisons show that the drag increment predicted for configuration 217 (Fig. 31a) agrees well at low lift coefficients at subsonic Mach numbers, whereas at the high lift coefficients and at the supersonic Mach numbers, the drag increment was generally underpredicted when individual increments were summed. This trend follows the general trend noted above, which was that the presence of stores at other armament stations generally increased the drag increment of a particular store or store configuration. However, the data for configuration 206 in Fig. 31b show that the drag increment predicted by summing individual increments agrees well with the total measured drag increment even at high lift coefficients, except at Mach number 1.3 where the drag increment was somewhat under-predicted. It appears that additional individual store data are needed before any definite conclusions can be made as to the validity of summing the drag increments of

individual stores to predict the total drag increment of an external store configuration of different stores at several armament stations. However, from the data available from these tests, it appears that summing the individual store drag increments did reasonably predict the total drag increment of a multiple carriage configuration at the low values of lift coefficient corresponding to cruise conditions.

4.4 EFFECT OF EXTERNAL STORE CONFIGURATIONS ON THE LATERAL-DIRECTIONAL STABILITY DERIVATIVES

Lateral-directional stability data were obtained for five external store configurations of the model F-15 aircraft. Data were obtained at 0-, 10-, 15-, and 20-deg angle of attack for configurations 201, 203, 206, and 209 and at 20-deg angle of attack for configuration 213. The lateral-directional data for configuration 201, which will be considered the baseline configuration, are presented in Fig. 32, and the lateral-directional derivatives calculated from these data are presented in Fig. 33. The data in Fig. 33 indicate a marked decrease in C_{n_β} with aircraft angle of attack for the clean configuration (201) with directional instability ($C_{n_\beta} < 0$) being noted at $\alpha = 20$ deg at Mach numbers 1.2 and 1.3. The data in this figure also show that, as the aircraft angle of attack was increased, an improvement in effective dihedral was experienced as indicated by the negative shift in C_{l_β} . Adding external stores to configuration 201 had the effect of shifting C_{n_β} negatively at the subsonic Mach numbers for all configurations tested, as can be seen from the data in Fig. 34. These data also show that the addition of external stores in general improved the dihedral effect of the F-15, producing more negative values of C_{l_β} . However, the TEWS and the SUU-30H/B stores for some conditions (Figs. 34b, c, and d) reduced the effective dihedral of the F-15.

5.0 SUMMARY OF RESULTS

Transonic Wind tunnel tests were conducted to determine the effect of external carriage of various configurations of stores on the aerodynamic characteristics of the F-15 aircraft. The tests were conducted with 0.05-scale models of the F-15 and external stores. The results of the analysis of the data from these tests in which the model moment reference point was constant at 25.65 percent of the mean aerodynamic chord are summarized as follows:

1. When compared with the low alpha inlet configuration, the high alpha inlet configuration showed a more negative zero lift pitching-moment coefficient, did not significantly change the static longitudinal stability, and exhibited slightly lower drag.

2. With the exception of the SUU-30H/B configuration (206) at Mach numbers 0.95 and 0.975, the effect of adding external stores to the F-15 model at armament stations 1 and 9, and 2 and 8 was always destabilizing with respect to static longitudinal stability and essentially independent of Mach number. In general, the stores produced a 2- to 3-percent chord change in static margin for the stores and store configurations tested.
3. Adding the 600-gal fuel tank to the F-15 model at armament station 5 generally produced a slight increase in static longitudinal stability.
4. Changes in static margins which were produced by adding external stores to the F-15 model at any armament station were generally always smaller when external stores were present at the other armament stations than without stores present at the other armament stations.
5. Summing the drag increments measured when individual stores were added to the F-15 model without other stores present reasonably predicted the total drag increment measured for multiple carriage store configurations at the low values of lift coefficients corresponding to cruise conditions. However, except at Mach number 1.3, summing the individual static margin increments overpredicted the total static margin increment, by as much as 50 percent in some cases.
6. Increasing the angle of attack reduced the static directional stability derivative for the clean configuration. However, the effective dihedral of the clean configuration was essentially constant for angles of attack up to 10 deg. Above 10-deg angle of attack, the the effective dihedral increased with increasing angle of attack.
7. At the subsonic Mach numbers, adding external stores to the clean configuration reduced the static directional stability derivative at each angle of attack for all configurations tested.
8. In general, the effective dihedral of the F-15 model was improved at each angle of attack when external stores were added to the clean configuration. Some degradation of effective dihedral was noted at some conditions when the F-15 model was carrying the Tactical Electronic Warfare Systems pods or the SUU-30H/B stores.

NOMENCLATURE

BL	Model butt line, in.
b	Model reference span, 25.62 in.
C_D	Drag coefficient. drag/ $q_\infty S$
ΔC_D	Incremental changes in drag coefficient caused by adding external stores, positive values indicate a drag increase (Values presented in Fig. 7 are referenced to configuration 201 at a C_L of 0.3 and $M_\infty = 0.6$.)
C_L	Lift coefficient, lift/ $q_\infty S$
\bar{C}	Centerline
C_Q	Rolling-moment coefficient referenced to WL 5.81 BL 0, rolling moment/ $q_\infty S b$
$C_{Q\beta}$	Effective dihedral, slope of a least-squares curve fit of the rolling-moment coefficient versus sideslip angle curve from $-4 \leq \beta \leq 4$ deg, per degree
C_m	Pitching-moment coefficient referenced to FS 27.86 (25.65-percent MAC), WL 5.81, BL 0, pitching moment/ $q_\infty S \bar{c}$
C_n	Yawing-moment coefficient referenced to FS 27.86 (25.65-percent MAC), WL 5.81, BL 0, yawing moment/ $q_\infty S b$
$C_{n\beta}$	Static directional stability derivative, slope of a least-squares curve fit of the yawing-moment coefficient versus sideslip angle curve from $-4 \leq \beta \leq 4$ deg, per degree
C_Y	Side-force coefficient, side force/ $q_\infty S$
$C_{Y\beta}$	Side-force derivative, slope of a least-squares curve fit of the side-force coefficient versus angle of sideslip curve from $-4 \leq \beta \leq 4$ deg, per degree
\bar{c} , MAC	Theoretical mean aerodynamic chord (Fig. 3), 9.564 in.
cg	Center of gravity, MS 27.86 (25.65-percent MAC), WL 5.81, BL 0
FS	Model fuselage station, in.
M_∞	Free-stream Mach number

P_t	Free-stream total pressure, psfa
q_∞	Free-stream dynamic pressure, psf
S	Model reference area, wing area, 1.52 ft ²
SM	Static margin, slope of a least-square curve fit of the pitching-moment coefficient versus lift coefficient curve from $-2 \leq a \leq 6$ deg, fraction of \bar{c} , negative when aft of cg
ΔSM	Incremental change in static margin caused by adding external stores, positive values indicate a destabilizing effect
WL	Model waterline from reference horizontal plane, in.
a	Wing chord (and model waterline) angle of attack, deg
a_f	Tunnel-flow and model-balance misalignment angle, deg, positive for flow upwash
β	Angle of sideslip, deg
