## NOVEMBER 23, 1992

92-2150

SUBJECT: SPRAYABLE SILICONE ABLATIVE COATING, GE PRODUCT CODE CPC-1050, POST LAUNCH EVALUATION ON LAUNCH COMPLEX 40, CAPE CANAVERAL AIR FORCE STATION

RELATED DOCUMENTATION: MTB-921-89

## 1.0 <u>SUMMARY</u>

An inspection was performed on 30 September and 01 October 1992, to assess the condition of Launch Complex 40 Umbilical Tower ablative coating after a launch of a Titan 34D missile. Photographic documentation of the post-launch condition was also gathered. Overall performance of CPC-1050 Silicone Ablative has been evaluated as excellent.

### 2.0 FOREWORD

2.1 Based on favorable results documented in MTB 921-89, the prime contractor for LC-40 Facilities Modification (Bechtel Job No. 20964, Contract No. KQO-804691) elected to topcoat the inorganic zinc primer on the Umbilical Tower (UT) with the subject silicone ablative coating. Specification T-002, GENERAL PAINTING, called for the following topcoat schedule:

Area of UT	Dry Film Thickness
Pipe Support Structure	125 MILS
Exposed Steel below El. 134'4" (Level 2)	125 MILS
Exposed Steel between El. 134'4" (Level 2) and El. 146'4" (Level 3)	80 MILS

- î -

92-2150

÷ 1

ŧ

2.2 As will become apparent in the results section, actual dry film thickness (DFT) readings of the coating varied considerably from those specified, both above and below. Whether these variations were due to locally generated changes not documented, or to other factors, could not be ascertained prior to the completion of this report. No adverse impact on the structural steel was identified as a result of this variation in ablative coating thickness.

ABBOTTAEROSPACE.COM

### 3.0 MATERIALS AND EOUIPMENT

- 3.1 The materials and equipment used for the application of the silicone ablative have been described in detail in MTB 921-89, paragraph 2.0.
- 3.2 DFT readings were obtained with a Microtest IV SM-3 gage (for coatings less than or equal to 100 MILS) or a Microtest IV SM-10 gage (for coatings greater than 100 MILS). DFT gages were field calibrated using manufacturer's supplied instructions.

## 4.0 TEST PROCEDURES

- 4.1 Test measurement points were identified on LC-40 UT and defuge piping support structures so that surfaces exposed to varying blast effects could be monitored. These areas were:
  - 1. South Face Level 4
  - 2. North Face Level 4
  - 3. East Face Level 4
  - 4. South Face Level 3
  - 5. North Face Level 3
  - 6. East Face Level 3
  - 7. South Face Level 2
  - 8. North Face Level 2
  - 9. East Face Level 2
  - 10. South Face Level 1
  - 11. East Face Level 1
  - 12. East Face Ground Level
  - 13. Deluge Pipe Supports
- 4.2 Film thickness readings were taken prior to and after the launch. The entire UT and launcher systems were inspected for damage, including areas not coated with the silicone ablative.

# 5.0 <u>RESULTS</u>

5.1 The following Table contains the results of the DFT readings, including a visual evaluation of the ablative coating surface after launch.

5.2 The ablative material applied to the structural steel on the CX-40 UT withstood the thermal and pressure shock loadings associated with the launch, exhibiting little or no loss of thickness due to ablation. Figure 1 shows an overall view of the UT. The arrow indicates the transition from the silicone ablative coating and the steel coated with 4-6 mils of inorganic zinc only. Approximately 30% of the surface of the silicone ablative on the east

Į

face was covered with a black, sooty material easily removed with finger pressure. The sooty material is probably the combustion product from organic material used in the launch pad area. Low pressure water washing can be used to remove this material.

ABBOTTAEROSPACE.COM

ECHNICAL LIBRARY

- 5.3 The ablative material film thickness, as measured, was not in accordance with the specification. Although no damage to the structural steel resulted in this case, proper application of the required thickness is important to control costs of installation and repair. Areas receiving substantially less material than specified can be expected to require a maintenance topcoat prior to the majority of the UT.
- 5.4 The application of the MARTYTE<sup>TM</sup> over the ablative shown in Figure 2 was not required. MARTYTE<sup>TM</sup> is a ceramic filled, amine-cured epoxy compound developed by Martin Marietta. Figure 3 details the interface of MARTYTE<sup>TM</sup> and the silicone ablative. While the silicone ablative remained virtually unaffected, the MARTYTE<sup>TM</sup> suffered spalling and delamination. The spalled MARTYTE<sup>TM</sup>, impacting against the silicone ablative, is believed responsible for some of the gouging seen in Figure 4.
- 5.5 Isolated areas near the northeast and southeast corners, where film thicknesses were well below specified, experienced ablation to bare metal. These areas might also have been abraded during the insertion of the mobile launch structure. Although the total area of this type damage was minor, an increase in specified film thickness is indicated. Figure 5 shows a typical example of this type of damage.
- 5.6 Isolated areas, between ground level and five feet above ground level, experienced total loss of ablative material and inorganic zinc primer. Figure 6 shows the west side of the deluge piping; Figure 7 shows the west side of the deluge piping support; and Figure 8 shows the deluge piping on the east side of the UT.
- 5.7 Portions of the deluge water nozzles penetrating the UT walls were protected with MARTYTE<sup>TM</sup> (See Figure 9). This time consuming process can be eliminated with the development of small unit repair kits, discussed further in paragraph 7.0.

1

## 6.0 <u>CONCLUSIONS</u>

6.1 Based on the findings of this inspection, the silicone ablative material applied to CX-40 UT showed little or no loss of thickness due to ablation.

TECHNICAL LIBRARY

ABBOTTAEROSPACE.COM

- 6.2 Due to the lack of damage to the silicone ablative, the application of MARTYTE<sup>™</sup> over the ablative was not required. The practice of protecting the deluge water nozzle penetrations with MARTYTE<sup>™</sup> is not required.
- 6.3 Instances of ablation to bare metalweredue to either insufficient application thickness or mechanical damage during installation of the mobile launcher.
- 6.4 The black sooty residue found after the launch was easily removed and not associated with the ablation process.
- 6.5 Despite the extreme heat conditions of the launch, the silicone ablative material retained its original color, protected the underlying steel, and remained virtually unaffected. The excellent performance characteristics significantly reduced the effort involved with the normal post-launch pad refurbishment.

### 7.0 <u>RECOMMENDATIONS</u>

- 7.1 In future applications, apply silicone ablative at 200 milsfrom ground level to Level 2 and 150 mils from Level 2 to the end of coverage on the east face of UT. Increase coverage around corners to 300 mils/200 mils respectively. Silicone ablative should be applied in a minimum of two colored coats, the first coat 60-75% of the total thickness. This will allow maintenance personnel easy evaluation for the need to topcoat.
- 7.2 Develop a repair kit capable of patching small nicks and gouges. Dual hypodermic type kits, similar to commercial glues is one possible approach. Such a repair kit could also be used to apply silicone ablative in areas such as the deluge nozzles seen in Figure 9. Alternately or in parallel, efforts to increase the toughness through reformulating should be investigated.

92-2150

ł

7.3 Future applicators should be trained to achieve a more uniform film thickness. Wide variation in applied thicknesses in the present case was probably caused by the lack of familiarity with the coating and the plural component spray rig required for application. Lack of control of film thickness will affect the materials cost, as well as jeopardize the underlying steel structure.

TECHNICAL LIBRARY

ABBOTTAEROSPACE.COM

7.4 Several areas, not coated with silicone ablative. should be coated in the future. Items include: Electrical panel blast shields (Figure 10); EAGE building doors (Figure 11); Piping supports of the south end of UT (Figure 12); Ladder at the southeast corner of UT (Figure 13); Launcher supports (figure 14); Deflector supports (Figure 15); and miscellaneous ground hardware (Figures 16 and 17). 19

### ACKNOWLEDGEMENT

The investigator wishes to acknowledge Mr. R. W. Dively of Johnson Controls World Services, Inc., for the contribution of the data, discussion, and photographs that proved invaluable in the preparation of this report.
