THE STABILITY UNDER LONGITUDINAL COMPRESSION OF FLAT
SYMMETRIC CORRUGATED-CORE SANDWICH PLATES WITH
SIMPLY SUPPORTED LOADED EDGES AND SIMPLY
SUPPORTED OR CLAMPED UNLOADED EDGES

By Paul Seide

SUMMARY

A theory for the elastic behavior of orthotropic sandwich plates is
used to determine the compressive-buckling-load parameters of flat sym-
metric corrugated-core sandwich plates with simply supported loaded edges
and simply supported or clamped unloaded edges. Charts are presented
for corrugated-core sandwich plates for which the transverse shear stiff-
ness in planes parallel to the axis of the corrugations may be assumed
infinite. The limits of validity of this assumption are investigated
for simply supported plates.

INTRODUCTION

Considerable work has been done on the problem of the stability of
sandwich plates with isotropic faces and isotropic non-stress-carrying
core materials such as end-grain balsa or cellular cellulose acetate.
The corrugated-core sandwich plate, which consists of a corrugated metal
sheet fastened between two flat sheets, is of a different type in that
the core has orthotropic flexural and transverse shear properties. The
transverse shear stiffness in planes parallel to the axis of the corru-
gations is usually many times the stiffness in planes perpendicular to
the axis of the corrugations and may be considered infinite for many
practical constructions. The flexural properties are such that the
corrugated core can to some extent resist bending moments applied in
planes parallel to the axis of the corrugations, whereas its resistance
to bending moments applied in planes perpendicular to the axis of the
corrugations is negligible.

The theory of reference 1, together with the physical constants
derived in reference 2, makes possible the determination of the elastic
over-all buckling loads of flat corrugated-core sandwich plates with
symmetric corrugated cores. By over-all buckling is meant buckling of
the sandwich plate as a whole, without regard to local buckling of the faces between corrugation crests or of the corrugation walls. In the present paper the theory is applied to the problem of the stability under longitudinal compression of flat symmetric corrugated-core sandwich plates with simply supported loaded edges and simply supported or clamped unloaded edges.

Stability criterions are derived for these two problems in an appendix. Numerical results are presented in the form of charts which show the variation of the compressive-buckling-load parameter with plate aspect ratio for different values of parameters involving the flexural and transverse shear stiffness of the corrugated core. For these charts the transverse shear stiffness in planes parallel to the axis of the corrugations was taken as infinite. The limits of validity of the charts for corrugated-core sandwich plates having finite transverse shear stiffness in both directions are investigated for simply supported plates. Some of the numerical results of the present paper have been published separately in references 3 and 4.

SYMBOLS

\( A, B, C \) coefficients in expressions for \( w, Q_x, \) and \( Q_y, \) respectively, for a plate with simply supported unloaded edges

\( A_i, B_i, C_i \) coefficients in expressions for \( w, Q_x, \) and \( Q_y, \) respectively, for a plate with clamped unloaded edges \((i = 1, 2, 3)\)

\( a \) plate length

\( b \) plate width

\( DQ_x, DQ_y \) transverse shear stiffnesses per unit width of a beam cut from plate in \( x- \) and \( y- \) directions, respectively (formulas and charts for calculation of \( DQ_x \) and \( DQ_y \) are given in reference 2)

\( E_C \) Young's modulus of elasticity of core material

\( E_S \) Young's modulus of elasticity of face material

\( h \) distance between middle surfaces of face sheets
\( I_c \)  
moment of inertia per unit width of corrugation cross section in planes perpendicular to x-axis, taken about sandwich-plate middle surface

\( I_s \)  
moment of inertia per unit width of faces, considered as membranes, taken about sandwich-plate middle surface \( \left( \frac{1}{2} t s h^2 \right) \)

\( m \)  
number of buckle half-waves in x-direction

\( N \)  
longitudinal compressive buckling load per unit width of sandwich plate.

\( n \)  
number of buckle half-waves in y-direction of a plate with simply supported unloaded edges

\( n_i \)  
arbitrary quantities in expressions for \( w, Q_x, \) and \( Q_y \) for a plate with clamped unloaded edges \( (i = 1, 2, 3) \)

\( Q_x, Q_y \)  
transverse shear forces in planes perpendicular to the x- and y-axes, respectively

\( t_s \)  
face thickness

\( w \)  
deflection of sandwich-plate middle surface

\( x, y \)  
coordinate axes (see fig. 1)

\( \mu_s \)  
Poisson's ratio of face material

\( \nabla^2 \)  
differential operator \( \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) \)

Parameters used in the presentation of results:

\( a/b \)  
plate aspect ratio

\( \frac{b^2 N}{\pi^2 E_s I_s} \)  
compressive-buckling-load parameter

\( \frac{E_c I_c}{E_s I_s} \)  
flexural-stiffness ratio
transverse-shear-flexibility parameters
\[
\frac{\pi E_S I_S}{b^2 D_{Qx}}, \quad \frac{\pi E_S I_S}{b^2 D_{Qy}}
\]
transverse-shear-stiffness ratio
\[
\frac{D_{Qx}}{D_{Qy}}
\]
For convenience, these parameters are abbreviated in the appendix as follows
\[\beta\]
plate aspect ratio \((a/b)\)
\[k\]
compressive-buckling-load parameter \(\left(\frac{b^2 N}{\pi E_S I_S}\right)\)
\[\eta\]
flexural-stiffness ratio \(\left(\frac{E_Q I_Q}{E_S \bar{I}_S}\right)\)
\[r_x, r_y\]
transverse-shear-flexibility parameters \(\left(\frac{\pi E_S I_S}{b^2 D_{Qx}}\right)\) and \(\left(\frac{\pi E_S I_S}{b^2 D_{Qy}}\right)\), respectively

CORRUGATED-CORE SANDWICH-PLATE THEORY

The sandwich-plate theory of reference 1 deals with elastic plates of continuous construction which have orthotropic flexural and transverse-shear properties. Straight lines in the plate that are originally perpendicular to the undeformed plate middle surface are assumed to remain straight but not necessarily perpendicular to the plate middle surface after bending occurs. The plate is also assumed to have no local deformations. This last assumption permits the analysis of only the over-all stability of sandwich plates.

Corrugated-core sandwich plates can be analyzed by this theory provided that limitations are imposed on the relative dimensions of the sandwich faces and of the core. The pitch of the core corrugations should be small compared with the plate width perpendicular to the axis of the corrugations so that the plate can be treated adequately as a continuous orthotropic medium. The thickness of the faces should be
small compared with the over-all plate thickness in order that bending of each face about its own middle surface may be neglected. The core should be sufficiently stiff so that changes in the plate thickness are negligible.

The investigations of reference 2 indicate that limitations should also be placed on the type of corrugated-core sandwich plate that may be analyzed by the sandwich-plate theory of reference 1. The Poisson’s ratios of the materials of the two faces must be equal, the neutral plane of bending of the faces alone must coincide with the plane passing through the centroidal axis of the corrugation cross section, and load resultants must be applied in specified planes between the plate faces. Symmetric corrugated-core sandwich plates - that is, plates with faces of equal thickness and of the same material and with a corrugated core having symmetrical corrugations - satisfy these conditions, provided that load resultants are applied in the plane of the plate middle surface.

RESULTS AND DISCUSSION

In the present paper the compressive buckling of flat symmetric corrugated-core sandwich plates with simply supported loaded edges and simply supported or clamped unloaded edges (see fig. 1) is investigated. For symmetric corrugated-core sandwich plates the elastic constants derived in reference 2 reduce to the relatively simple forms given in the appendix. The solution can be expressed in terms of six nondimensional quantities

\[
\frac{b^2N}{\pi^2E_S T_S} \quad \text{compressive-buckling-load parameter}
\]

\[
a/b \quad \text{plate aspect ratio}
\]

\[
\frac{E_G T_G}{E_S T_S} \quad \text{flexural-stiffness ratio}
\]

\[
\frac{\pi^2E_G T_G}{b^2D_Gx}, \frac{\pi^2E_S T_S}{b^2D_Gy} \quad \text{transverse-shear-flexibility parameters}
\]

\[
\mu_S \quad \text{Poisson's ratio of face material}
\]
Stability criterions which relate these six parameters for the two problems considered are derived in the appendix (equation (6) for plates with simply supported unloaded edges and equations (11) and (15) for plates with clamped unloaded edges).

For many practical structures the transverse shear stiffness in planes parallel to the axis of the corrugations is very much greater than the transverse shear stiffness in planes perpendicular to the axis of the corrugations and may be assumed infinite. In the present paper the corrugations are taken parallel to the x-axis, in which case \( D_{QX} \) is the transverse shear stiffness that may be assumed infinite. The transverse-shear-flexibility parameter \( \frac{\pi^2 E_S I_S}{b D_{QX}} \) is then equal to zero and the stability criterions reduce to equation (7) for plates with simply supported unloaded edges and to equations (16) and (17) for plates with clamped unloaded edges.

Charts have been prepared for the case of infinite \( D_{QX} \) and show the variation of the compressive-buckling-load parameter \( \frac{b^2 N}{\pi^2 E_S I_S} \) with plate aspect ratio \( a/b \) for the transverse-shear-flexibility parameter \( \frac{\pi^2 E_S I_S}{b^2 D_{QY}} \) equal to 0, 0.1, 0.25, 0.5, 1.0, and \( \infty \) and the flexural-stiffness ratio \( \frac{E_S I_S}{E_I I_S} \) equal to 0, 0.5, and 1.0. Poisson's ratio for the face material \( \mu_S \) has been taken as 1/3. In figure 2, the charts for finite plates with simply supported unloaded edges are presented. The compressive-buckling-load parameter for infinitely long plates with simply supported edges is plotted against the transverse-shear-flexibility parameter \( \frac{\pi^2 E_S I_S}{b^2 D_{QY}} \) in figure 3. These curves were obtained by replottting the minimum values of compressive-buckling-load parameter of the curves of figure 2. Similar charts are presented for plates with clamped unloaded edges in figures 4 and 5.

The trends of the curves of figures 2 to 5 are similar in some respects to those of the curves of references 5 and 6 for isotropic sandwich plates. As the transverse-shear-flexibility parameter \( \frac{\pi^2 E_S I_S}{b^2 D_{QY}} \) increases, the compressive-buckling-load parameters are materially
reduced. The reductions are greater for plates with clamped unloaded edges, because the effect of edge clamping is lessened with increasing transverse shear flexibility and the values of the compressive-buckling-load parameter for plates with clamped unloaded edges approach those of plates with simply supported unloaded edges. Because the corrugated-core sandwich plates are assumed to have unequal transverse shear stiffnesses, the transverse shear stiffness $D_{QY}$ being greater than the transverse shear stiffness $D_{QX}$, the reductions in compressive-buckling-load parameters are not so great as those for isotropic-core sandwich plates. For example, for the case of a corrugated-core sandwich plate with infinite transverse shear stiffness $D_{QX}$ and zero transverse shear stiffness $D_{QY}$, the compressive-buckling-load parameter is finite, rather than being equal to zero, and varies with plate aspect ratio.

The longitudinal buckle half wave lengths of isotropic-core sandwich plates decrease with decreasing transverse shear stiffness; the buckle wave lengths of corrugated-core sandwich plates with infinite transverse shear stiffness $D_{QX}$, however, tend to increase with decreasing transverse shear stiffness $D_{QY}$. Calculations indicate that a corrugated-core sandwich plate with zero transverse shear stiffness $D_{QY}$ buckles in only one longitudinal half wave, regardless of the plate aspect ratio. The buckle half wave lengths of infinitely long corrugated-core sandwich plates with simply supported edges remain relatively constant over a large range of values of the transverse-shear-flexibility parameter and flexural-stiffness ratio. The half wave length is approximately equal to the plate width for values of the transverse-shear-flexibility parameter $\frac{\pi^2 E_s}{b^2 D_{QY}}$ varying from 0 to 1.0 and for values of the flexural-stiffness ratio varying from 0 to 1.0. In this range the half wave length is 1.0 to 1.3 times the plate width. For plates with clamped unloaded edges, the half wave length of buckle varies somewhat more (from 0.66 to 1.2 times the plate width).

**EFFECT OF FINITE TRANSVERSE SHEAR STIFFNESS $D_{QX}$**

Although it is customary to assume in the analysis of corrugated-core sandwich plates that the transverse shear stiffness $D_{QX}$ is infinite, little or no information as to the limits of validity of this assumption is available. Calculations have been made for the present
paper to determine the minimum value of \( \frac{D_{Q_x}}{D_{Q_y}} \) for which the assumption of infinite \( D_{Q_x} \) is adequate.

Values of \( \frac{b^2N}{\pi^2 E_5 I_S} \) for infinitely long simply supported plates with various values of \( \frac{D_{Q_x}}{D_{Q_y}} \) are shown in figures 6(a) to 6(c). These values were obtained by plotting values of \( \frac{b^2N}{\pi^2 E_5 I_S} \) given by equation (6) for several values of the buckle aspect ratio \( a/mb \) and by picking off the minimum of the curve so defined. This procedure was repeated for various sets of values of \( \frac{E_5 I_S}{b^2 D_{Q_y}} \), \( \frac{E_5 L_C}{E_5 I_S} \), and \( \frac{\pi^2 E_5 I_S/b^2 D_{Q_y}}{\pi^2 E_5 I_S/b^2 D_{Q_x}} \) or \( \frac{D_{Q_x}}{D_{Q_y}} \).

Since the transverse-shear-flexibility parameter \( \frac{\pi^2 E_5 I_S}{b^2 D_{Q_y}} \) for plates of practical dimensions is less than about 0.5, it may be concluded that values of \( \frac{b^2N}{\pi^2 E_5 I_S} \) are given with little error by the curve for \( D_{Q_x} \) equal to infinity \( \left( \frac{D_{Q_x}}{D_{Q_y}} = \infty \right) \) if the transverse-shear-stiffness ratio \( \frac{D_{Q_x}}{D_{Q_y}} \) is greater than about 10. Calculations indicate that this conclusion applies also to plates of finite length, provided that the plate aspect ratio \( a/b \) is not less than about 0.6.

Because of the complexity of the stability criterion for compressive buckling of corrugated-core sandwich plates with simply supported loaded edges and clamped unloaded edges (equations (11) and (15)), no attempt was made to obtain information as to the limits of validity of the assumption of infinite transverse shear stiffness \( D_{Q_x} \). It seems reasonable, however, to expect a transverse-shear-stiffness ratio \( \frac{D_{Q_x}}{D_{Q_y}} \) of about 10 to be a lower limit for the assumption to be adequate.
CONCLUDING REMARKS

The over-all stability of flat symmetric corrugated-core sandwich plates with simply supported loaded edges and simply supported or clamped unloaded edges has been investigated by the use of the orthotropic-sandwich-plate theory of NACA Rep. 899 in conjunction with the physical constants for symmetric corrugated-core sandwich plates derived in NACA TN 2289. Charts showing the variation of the compressive-buckling-load coefficient with plate aspect ratio, transverse-shear-flexibility parameter, and flexural-stiffness ratio have been prepared for plates for which the transverse shear stiffness in planes parallel to the axis of the corrugations can be assumed to be infinite.

By use of the more general equations derived for corrugated-core sandwich plates with finite transverse-shear stiffness in both directions, it is concluded that these charts may be considered adequate for plates of practical dimensions for which the transverse shear stiffness in planes parallel to the axis of the corrugations is 10 or more times the transverse shear stiffness in planes perpendicular to the axis of the corrugations, provided that the plate aspect ratio is greater than about 0.6.

APPENDIX

DERIVATION OF STABILITY CRITERIONS

Differential Equations

Equations that may be used for the determination of the compressive buckling loads of flat symmetric corrugated-core sandwich plates are given in reference 1. The seven physical constants of corrugated-core sandwich plates required for the use of these equations are derived in reference 2 and are as follows for plates having thin faces of equal thickness and symmetrical cores

\[
\begin{align*}
D_x &= E_S \bar{I}_S \left(1 + \frac{E_G \bar{I}_G}{E_S \bar{I}_S}\right) \\
D_y &= E_S \bar{I}_S \left[1 + \frac{E_G \bar{I}_G}{E_S \bar{I}_S} \right] \left[1 + \frac{1 - \mu_S^2}{E_G \bar{I}_G} \right] \\
D_{xy} &= E_S \bar{I}_S \left(\frac{1}{1 + \mu_S}\right) \\
\mu_x &= \mu_S \\
\mu_y &= \mu_S \left[\frac{1}{1 + \frac{(1 - \mu_S^2)E_G \bar{I}_G}{E_S \bar{I}_S}}\right] \\
D_{Q_x} &= \\
D_{Q_y} &= (1)
\end{align*}
\]

The formulas for the calculation of $D_{Q_x}$ and $D_{Q_y}$, derived in reference 2, are rather cumbersome and are not presented here.
The differential equations of reference 1 are given for the present problem as

\[
N \frac{\partial^2 w}{\partial x^2} - \frac{\partial Q_x}{\partial x} - \frac{\partial Q_y}{\partial y} = 0
\]

\[
\left( \frac{E_S T_S}{1 - \mu_S^2} \frac{\partial}{\partial x} \nabla^2 w + E_G T_G \frac{\partial^3}{\partial x^3} \right) w + \left[ \frac{1 - \frac{E_S T_S}{2(1 + \mu_S)} \frac{1}{D_{Q_x}} \frac{\partial^2}{\partial x \partial y^2} -}{1 - \mu_S^2} \frac{\partial}{\partial y} \nabla^2 w \right] Q_x - \frac{E_S T_S}{2(1 - \mu_S)} \frac{1}{D_{Q_y}} \frac{\partial^2 Q_y}{\partial x \partial y} = 0
\]

\[
\frac{E_S T_S}{1 - \mu_S^2} \frac{\partial}{\partial y} \nabla^2 w - \frac{E_S T_S}{2(1 - \mu_S)} \frac{1}{D_{Q_x}} \frac{\partial^2 Q_x}{\partial x \partial y} + \left[ \frac{1 - \frac{E_S T_S}{2(1 + \mu_S)} \frac{1}{D_{Q_y}} \frac{\partial^2}{\partial x \partial y^2} -}{1 - \mu_S^2} \frac{\partial}{\partial y} \nabla^2 w \right] Q_y = 0
\]

Simply Supported Unloaded Edges

The conditions that are satisfied at the edges of the simply supported plate (fig. 1(a)) are those of zero deflection of the middle surface, zero moment normal to the edges, and no relative movement parallel to the edges of points in the boundary. These conditions may be expressed in terms of \(w\), \(Q_x\), and \(Q_y\), at \(x = 0\) and \(x = a\), as

\[
w = \frac{\partial}{\partial x} \left( \frac{\partial w}{\partial x} - \frac{Q_x}{D_{Q_x}} \right) + \frac{\mu_S}{1 + (1 - \mu_S^2) \frac{E_G T_G}{E_S T_S}} \frac{\partial}{\partial y} \left( \frac{\partial w}{\partial y} - \frac{Q_y}{D_{Q_y}} \right) \frac{Q_y}{D_{Q_y}} = 0 \quad (3a)
\]
and, at \( y = 0 \) and \( y = b \), as

\[
\begin{align*}
\dot{w} &= \frac{\partial}{\partial y} \left( \frac{\partial w}{\partial y} - \frac{\partial y}{\partial Q_y} \right) + \mu_s \frac{\partial}{\partial x} \left( \frac{\partial w}{\partial x} - \frac{\partial x}{\partial Q_x} \right) = \frac{\partial Q_x}{\partial Q_y} = 0 \quad (3b)
\end{align*}
\]

Functions that satisfy these boundary conditions are

\[
\begin{align*}
w &= A \sin \frac{\max}{a} \sin \frac{\max y}{b} \\
Q_x &= B \cos \frac{\max}{a} \sin \frac{\max y}{b} \\
Q_y &= C \sin \frac{\max}{a} \cos \frac{\max y}{b}
\end{align*}
\]

(4)

The differential equations will be satisfied also if the following set of simultaneous homogeneous equations, obtained by substituting equations (4) into equations (2) and rearranging terms, is satisfied:

\[
\begin{align*}
\frac{m^2}{\beta^2} k_A - \frac{m}{\beta} \frac{1}{E S^{\frac{1}{2}}} (b)^3 C - n \frac{1}{E S^{\frac{1}{2}}} (b)^3 C &= 0 \\
\frac{m}{\beta} \left\{ n^2 + \frac{m^2}{\beta^2} \left[ \frac{1}{E S^{\frac{1}{2}}} (b)^3 C - \frac{1}{E S^{\frac{1}{2}}} (b)^3 C \right] \right\} - n \frac{1}{E S^{\frac{1}{2}}} (b)^3 C &= 0 \\
\frac{n}{(\beta^2 + n^2)} A - \frac{1 + \mu_s}{2} n \frac{m}{\beta} r_x \frac{1}{E S^{\frac{1}{2}}} (b)^3 C - \\
\left[ 1 - \mu_s^2 + \left( \frac{1 - \mu_s}{2} \frac{n^2}{\beta^2} + n^2 \right) r_y \frac{1}{E S^{\frac{1}{2}}} (b)^3 C &= 0
\end{align*}
\]

(5)
The condition that \( A, B, \) and \( C \) have values other than zero—that is, that the determinant of their coefficients in equations (5) vanish—yields the stability criterion for simply supported corrugated-core sandwich plates under longitudinal compression

\[
\begin{align*}
\left\{ \frac{\left( \frac{m}{\beta} + n^2 \frac{\beta}{m} \right)^2}{\eta} \left[ \frac{(1 - \mu_\beta^2)}{2} \right] \left( \frac{m^2}{\beta^2} \right) + \left[ \frac{1}{2(1 + \mu_\beta)} \left( \frac{m}{\beta} + n^2 \frac{\beta}{m} \right)^2 \right] \right\} \\
\eta \left( n^2 + \frac{1 - \mu_\beta}{\beta} \right) \left( n^2 r_x + \frac{m^2}{\beta^2} r_y \right)
\end{align*}
\]

\[
k = \frac{1 - \mu_\beta^2 + \left[ \frac{1 - \mu_\beta}{2} n^2 + \frac{m^2}{\beta^2} + (1 - \mu_\beta^2) \frac{m^2}{\beta^2} \right] r_x + \left[ n^2 + \frac{1 - \mu_\beta}{\beta} \frac{m^2}{\beta^2} \right] r_y + \left[ \frac{1}{2(1 + \mu_\beta)} \left( \frac{m^2}{\beta^2} + n^2 \right)^2 \right] + \eta \frac{m^2}{\beta^2} \left( n^2 + \frac{1 - \mu_\beta}{\beta} \frac{m^2}{\beta^2} \right) r_x r_y}
\]

In the analysis of corrugated-core sandwich plates in which the corrugations are oriented in the direction of the \( x \)-axis, it is often assumed that \( D_{0x} \) is infinite. Then \( r_x \) is zero and the stability criterion is simplified to

\[
k = \frac{\left( \frac{m}{\beta} + n^2 \frac{\beta}{m} \right)^2}{1 - \mu_\beta^2 + \frac{n^2}{r_y} + \frac{1}{2(1 + \mu_\beta)} \frac{m^2}{\beta^2}} + \eta \frac{m^2}{\beta^2}
\]

(7)

When equation (6) or equation (7) is used, \( m \) and \( n \) are assigned different integral values until the lowest value of the compressive-buckling-load parameter \( k \) is obtained. Computations indicate that \( n \) should always be given the value \( 1 \) in these calculations so that the corrugated-core sandwich plate buckles with one sinusoidal half-wave in the \( y \)-direction.
Clamped Unloaded Edges

In the problem for plates with clamped unloaded edges (fig. 1(b)), the conditions that are satisfied along the simply supported edges are those of zero deflection of the middle surface, zero moment normal to the edges, and zero relative movement parallel to the edges of points in the boundary. These conditions are expressed by equation (3a). Along the clamped edges, the boundary conditions are those of zero deflection of the middle surface, zero relative movement normal to the edges of points in the boundary, and zero relative movement parallel to the edges of points in the boundary. At \( y = \pm \frac{b}{2} \),

\[
v = \frac{\partial^2 w}{\partial y^2} - \frac{Q_y}{D} = \frac{Q_x}{D} = 0
\]  

(8)

Solutions of the differential equations (2) for the middle-surface deflection \( w \) and the shear forces \( Q_x \) and \( Q_y \) exist in the form

\[
\begin{align*}
w &= \sin \frac{mx}{a} \sum_i A_i \cosh \frac{\pi n_i y}{b} \\
Q_x &= \cos \frac{mx}{a} \sum_i B_i \cosh \frac{\pi n_i y}{b} \\
Q_y &= \sin \frac{mx}{a} \sum_i C_i \sinh \frac{\pi n_i y}{b}
\end{align*}
\]  

(9)

where values of \( n_i, A_i, B_i, \) and \( C_i \) are to be determined from the differential equations (2). Equations (2) are satisfied by equations (9) if, for each value of \( i \), the following set of simultaneous equations is satisfied:

\[
\frac{m^2}{\beta^2} kA_1 - \frac{m}{\beta} \frac{1}{\sqrt{E_s T}} \left( \frac{b}{\pi} \right)^3 B_i + n_i \frac{1}{E_s T} \left( \frac{b}{\pi} \right)^3 C_i = 0
\]  

(10a)
\[
\frac{m}{\beta} \left\{ n_1^2 - \frac{m^2}{\beta^2} \left[ 1 + (1 - \mu_s^2)\eta \right] \right\} A_1 + \left( 1 - \mu_s^2 - \frac{1}{2} \frac{\mu_s}{n_1^2} \right) \]

\[
\frac{m^2}{\beta^2} \left[ 1 + (1 - \mu_s^2)\eta \right]_{\gamma}^{\gamma_x} \left( \frac{1}{E_s I_s} \left( \frac{b}{\pi} \right)^3 B_1 - \frac{1 + \mu_s}{2} n_1 \frac{m}{\beta} \frac{r_y}{E_s I_s} \left( \frac{b}{\pi} \right)^3 C_1 = 0 \right) (10b)
\]

\[
n_1 \left( \frac{m^2}{\beta^2} - n_1^2 \right) A_1 - \frac{1 + \mu_s}{2} n_1 \frac{m}{\beta} r_x \frac{1}{E_s I_s} \left( \frac{b}{\pi} \right)^3 B_1 - \left( 1 - \mu_s^2 + \left( \frac{1 - \mu_s}{2} \frac{m^2}{\beta^2} - n_1^2 \right) r_y \right) \frac{1}{E_s I_s} \left( \frac{b}{\pi} \right)^3 C_1 = 0 \right) (10c)
\]

The condition that \( A_1, B_1, \) and \( C_1 \) have values other than zero - that is, that the determinant of their coefficients in equations (10) vanish - yields an equation for the determination of \( n_1 \)

\[
\left[ \frac{1}{2(1 + \mu_s)} \right]_{\gamma}^{\gamma_x} n_1^6 + \left[ 1 + \frac{1}{2(1 + \mu_s)} \frac{m^2}{\beta^2} r_y + \left( \frac{1}{1 + \mu_s} + \eta \right) \frac{m^2}{\beta^2} r_x - \right]
\]

\[
\frac{1}{2(1 + \mu_s)} \frac{m^2}{\beta^2} kr_x r_y \right] n_1^4 + \frac{m^2}{\beta^2} \left( \frac{1}{1 + \mu_s} + \eta \right) \frac{m^2}{\beta^2} - k \right) r_y + \]

\[
\frac{1 - \mu_s}{2} \left( \frac{1}{1 - \mu_s^2} + \eta \right) \frac{m^2}{\beta^2} - k \right) r_x - \left( \frac{1}{1 + \mu_s} + \eta \right) \frac{m^2}{\beta^2} kr_x r_y \right] n_1^2 + \]

\[
\frac{m^2}{\beta^2} \left[ 1 + \frac{1}{2(1 + \mu_s)} \frac{m^2}{\beta^2} r_y \right] \left( 1 - \mu_s^2 \right) r_x - \]

\[
\frac{m^2}{\beta^2} \left[ 1 + (1 - \mu_s^2)\eta \right] (1 - kr_x) \right] = 0 \] (11)
Thus \( n_1 \) has the values \( \pm n_1, \pm n_2, \) and \( \pm n_3, \) the six roots of equation (11). Only the positive roots need be considered. Each of the coefficients \( B_1 \) and \( C_1 \) may be given in terms of the corresponding coefficient \( A_1. \) From equations (10a) and (10c), the following relations are obtained:

\[
\begin{align*}
\frac{1}{E_S T_S} \int_{\pi}^{b} \frac{1}{r} b_1 = \lambda_1 A_1 \\
\frac{1}{E_S T_S} \int_{\pi}^{b} \frac{1}{r} c_1 = -\phi_1 A_1
\end{align*}
\]

(12)

where

\[
\lambda_1 = \frac{k}{m} n_1^2 - \frac{m^2}{\beta^2} + \frac{1 + \mu_S}{2} \frac{m^2}{\beta^2} k r_x
\]

\[
\phi_1 = \frac{n_1^2 - \frac{m^2}{\beta^2} + \frac{1 + \mu_S}{2} \frac{m^2}{\beta^2} k r_x}{1 - \mu_S^2 + \left(\frac{1 - \mu_S}{2} \frac{m^2}{\beta^2} - n_1^2\right) r_y + \frac{1 + \mu_S}{2} n_1^2 r_x}
\]

Equation (9) may now be written as

\[
v = \sin \frac{\max}{a} \left( A_1 \cosh \frac{\pi n_1 y}{b} + A_2 \cosh \frac{\pi n_2 y}{b} + A_3 \cosh \frac{\pi n_3 y}{b} \right)
\]

\[
Q_x = \frac{1}{E_S T_S} \int_{\pi}^{b} \frac{1}{r} b_1 \cos \frac{\max}{a} \left( \lambda_1 A_1 \cosh \frac{\pi n_1 y}{b} + \lambda_2 A_2 \cosh \frac{\pi n_2 y}{b} + \lambda_3 A_3 \cosh \frac{\pi n_3 y}{b} \right)
\]

(13)

\[
Q_y = -\frac{1}{E_S T_S} \int_{\pi}^{b} \frac{1}{r} c_1 \sin \frac{\max}{a} \left( \phi_1 A_1 \sinh \frac{\pi n_1 y}{b} + \phi_2 A_2 \sinh \frac{\pi n_2 y}{b} + \phi_3 A_3 \sinh \frac{\pi n_3 y}{b} \right)
\]
Equations (13) already satisfy the boundary conditions along the simply supported edges (equation (3a)). The boundary conditions along the clamped edges (equation (8)) must now be satisfied. The substitution of equations (13) into equation (8) yields the following set of equations:

\[
\begin{align*}
A_1 \cosh \frac{\pi n_1}{2} + A_2 \cosh \frac{\pi n_2}{2} + A_3 \cosh \frac{\pi n_3}{2} &= 0 \\
\lambda_1 A_1 \cosh \frac{\pi n_1}{2} + \lambda_2 A_2 \cosh \frac{\pi n_2}{2} + \lambda_3 A_3 \cosh \frac{\pi n_3}{2} &= 0 \\
(n_1 + \phi_1 r_1 y) A_1 \sinh \frac{\pi n_1}{2} + (n_2 + \phi_2 r_2 y) A_2 \sinh \frac{\pi n_2}{2} + \\
(n_3 + \phi_3 r_3 y) A_3 \sinh \frac{\pi n_3}{2} &= 0
\end{align*}
\]  

(14)

In order to assure the existence of values of \( A_1, A_2, \) and \( A_3 \) other than zero, the determinant of the coefficients of \( A_1, A_2, \) and \( A_3 \) is set equal to zero. When the determinant is expanded, the following equation is obtained:

\[
\begin{align*}
(\lambda_3 - \lambda_2)(n_1 + \phi_1 r_1 y) \tanh \frac{\pi n_1}{2} + (\lambda_1 - \lambda_3)(n_2 + \phi_2 r_2 y) \tanh \frac{\pi n_2}{2} + \\
(\lambda_2 - \lambda_1)(n_3 + \phi_3 r_3 y) \tanh \frac{\pi n_3}{2} &= 0
\end{align*}
\]  

(15)

Equation (15) in conjunction with equation (11) is the criterion for the compressive buckling of corrugated-core sandwich plates with simply supported loaded edges and clamped unloaded edges.

When values of the compressive-buckling-load-parameter \( k \) are computed with equations (11) and (15), a trial and error process is used. For given values of \( \beta, r_x, r_y, \) and \( \eta, \) a value of \( k \) is assumed and \( m \) is assigned some integral value. Equation (11) is solved to give the values of \( n_1, n_2, \) and \( n_3. \) These values are then substituted into equation (15). If the left-hand side of equation (15) does not
vanish, other values of \( k \) must be chosen and the process repeated. This procedure yields a series of values of \( k \) and corresponding values of the left-hand side of equation (15). The correct value of \( k \) may now be obtained by plotting these values as ordinate and abscissa and picking off the value of \( k \) at which the left-hand side of equation (15) is equal to zero. The entire process is then repeated for other integral values of \( m \) until the lowest value of \( k \) is obtained.

For the case of infinite \( D_{eq} \), the following stability criterion is obtained:

\[
\frac{n_1}{1 - \mu_S^2 + \left(\frac{1 - \mu_S}{\beta^2} - n_1^2\right)R_y} \tanh \frac{n_1}{2} = 0
\]

\[
\frac{n_2}{1 - \mu_S^2 + \left(\frac{1 - \mu_S}{\beta^2} - n_2^2\right)R_y} \tanh \frac{n_2}{2} = 0 \quad (16)
\]

where \( n_1 \) and \( n_2 \) are the positive values of the roots \( \pm n_1 \) and \( \pm n_2 \) of the equation

\[
\left[ 1 + \frac{1}{2(1 + \mu_S)} \frac{m^2}{\beta^2} R_y \right] n_1^4 - \frac{m^2}{\beta^2} \left[ 2 + \left(\frac{1}{1 + \mu_S} + \eta \right) \frac{m^2}{\beta^2} \right] R_y \left[ 1 + \frac{m^2}{\beta^2} \right] n_1^4 = 0
\]

\[
\frac{m^2}{\beta^2} \left[ 1 + \frac{1}{2(1 + \mu_S)} \frac{m^2}{\beta^2} R_y \right] \left\{ (1 - \mu_S^2)k - \frac{m^2}{\beta^2} \left[ 1 + (1 - \mu_S^2)\eta \right] \right\} = 0 \quad (17)
\]

The same procedure is used in solving equations (16) and (17) for values of \( k \) as is used for equations (11) and (15).
